- What did you do?
 - Along with my teammates Will and Yihyun, we defined what redundancies are, proposed 3 types of redundancies, as well as proposed algorithms for finding these redundancies. I worked primarily on the first type of redundancy, “Calls taking longer than they should”. I thought of two subtypes of the redundancy and proposed a data-based algorithm for identifying these redundancies in the data, as well as identifying the key challenges that the algorithms would have to address to help guide next steps.
- How does it help the project?
 - My work helps the project by clearly defining what redundancies are and by proposing algorithms to detect them, specifically for cases where calls take longer than expected. This creates a concrete framework for identifying the problem that our client is facing through the data and guides the next phase of analysis and solution development.
- Issues faced (if any): N/A
- Attempts to resolve issues (if any): N/A
- Issues resolved (if any): N/A
- Next steps
 - There are a few tasks I hope to work on. Firstly, I would like to deep dive into the redundancy of “Calls taking longer than they should”.
 - For the first subtype, I would like to carry out the algorithm and calculate idle time accurately adjusting for other factors. A good first step would be calling and recording the time it took for each prompt. I am not entirely sure how to adjust for factors other than prompt length (ex: time of the day).

- For the second subtype, I would like to start by just identifying a few (maybe only one or two) instances of important final nodes. I would like to implement the algorithm where we find the set of all paths and the average time taken by each path to reach that final node and output those paths that seem to take the most time.
- o Additionally, I would also like to help implement the algorithms needed to identify repeated processes (second type of redundancy). Additionally, I would like to think of the kind of data structure we should use to represent our data, especially since our algorithm for identifying repeated processes relies on the notion of parent-child nodes, as well as cycles.
- o The above goals I've mentioned comprise of a lot of content. Since quality typically beats quantity, it may be beneficial for me/my team to focus deeply on only one of the goals.
- References (Mention if you built up on someone else's work): We referenced an academic paper that suggested that people can only retain 3-5 meaningful things in their minds at once. The citation is as below:
